THE CENTER FOR WORKFORCE HEALTH AND PERFORMANCE

## About the Center for Workforce Health and Performance

The Center for Workforce Health and Performance is a hub of information for research reports, educational resources, technical assistance, and a variety of evidence-based information sources on a healthy and high-performing workforce. CWHP fosters the use of evidence to promote the value of healthy, engaged and high-performing workers to employers, communities and society at large. By developing knowledge about workforce health and performance improvement, and disseminating it widely through scientific and educational forums, CWHP contributes to the adoption of evidence-based policies and practices that support a healthier, happier and higher-performing workforce, a healthier economy and, in turn, healthier and more productive communities.

## Background

PERIPHERAL ARTERIAL DISEASE (PAD) affects approximately 8.5 million Americans $\geq 40$ years and prevalence increases with increasing age. ${ }^{1}$ The most common symptom of PAD is leg pain associated with walking or other mild activities and is relieved with rest. ${ }^{2}$ This initial stage of pain symptoms is referred to as intermittent claudication (IC) and is the result of insufficient blood supply to the extremities due to fatty plaque build-up in the vessels. ${ }^{3}$ Symptoms of pain with walking can also occur in the buttock, hip, thigh, or calf.4,5 Lower-extremity functioning can decrease over time and can reach a point where individuals may feel pain even at rest. ${ }^{6,7}$ Given the disease mechanics and symptomatology, it makes sense that patients who suffer from IC have a low health-related quality of life (HRQoL) and functional impairment of their daily activities. ${ }^{8,9,10}$

There is a concern for patients presenting for medical attention with symptoms of IC considering the limitations that may be placed on their work and lifestyle. ${ }^{11,12}$ Body pain and a reduction in physical functioning strongly contribute to a reduction in HRQoL in patients with PAD and the burden of this disease has been well-documented. ${ }^{13,14}$

There is very little published research, however, on the impact of PAD on work-related activities despite there being many patients with PAD who still work. Of the few assessments, one small study of patients diagnosed with stage II PAD, physically active at the time of disease manifestation, reported that arterial disease affected their professional activity: $45.4 \%$ ( $n=45$ ); changed their activity: 28.9\% (n=13); required partial suspension of their activity $26.7 \%$ ( $n=12$ ); or all professional activities had ceased: $44.4 \%$ ( $n=20$ ). Changes in professional activity comprised invalidity (36.2\%), prolonged sick
leave (25.5\%), premature retirement (14.9\%), sick leave (17\%), unemployment (6.4\%), reduction in long-distance travel (4.3\%), change of job (8.5\%) or salary reduction (2.1\%). ${ }^{15}$

Data from the 2010 European National Health and Wellness Survey (NHWS) (5EU), ( $N=57,805$ ) and the 2010 U.S. NHWS ( $N=75,000$ ) (US), both self-administered Internet surveys, showed patients with self-reported PAD had greater overall work impairment when compared with individuals who did not report having PAD (5EU: $38.27 \%$ vs. $27.48 \%$; US: $23.89 \%$ vs. 14.26\%) (both p<0.05). Among the HRQoL questionnaires administered in this analysis was an assessment of work productivity. This questionnaire covered four metrics: absenteeism, presenteeism, overall work productivity loss and activity impairment. Subjects who worked while diagnosed with PAD reported significantly greater levels of interruption of work activities in all the above listed domains compared with those without PAD (all categories $\mathrm{p}<0.05$ ) in both the

US and Europe. ${ }^{16}$ Outside of these studies, very little is known about the effect of PAD on rates of work productivity loss.

Peripheral Arterial Disease symptoms are expected to affect the patient's ability to function at a high capacity in the work environment. Muscle cramps, pain and movement difficulty may affect performance on the job and a pose increased safety risks in certain occupations. Attendance may also suffer as individuals use sick leave while their symptoms resolve or for provider visits to access treatment. If a major event such as stroke or heart attack does occur, we can expect periods of work disability in which the individual recuperates before being able to return to work. In all cases, whether job performance declines, lower attendance or periods of work disability, these outcomes represent the employee's lowered function in the workplace and, accordingly, are associated with additional costs above and beyond the cost of treatment (or lack thereof) to the employer.

## Study Approach

THIS STUDY WILL DESCRIBE the association of PAD severity with work-related outcomes including short-term work disability incidence and duration. If the incidence and/or duration of short-term work disability can be lessened, we would expect costs related to work disruption and wage replacement to also decrease. These broader outcomes have benefits for both employers (lower business costs) and employees (lower lost wages).

The study aims to describe the relationship between work-related outcomes among the following two groups: 1) Mild cases - People with a PAD diagnosis only but no PAD procedures/treatment, 2) Moderate/severe cases - People with a PAD diagnosis and PAD procedures/treatment. Mild and moderate/severe cases are defined as outlined in Figure 1.77,18,19,20

## Data and Sample Selection

DATA FOR THE STUDY COME FROM a custom database from Truven Health Analytics, an IBM company (Truven), including their commercial claims (medical and pharmacy claims) and health and productivity management data. These data include all employers between 2008 and 2012 that provided Truven any health and productivity management data. In addition, benefit eligibility files are available
to establish both the incidence of PAD in these employee populations, the prevalence of service system use and the incidence of work disability.

Among those eligible for both medical benefits and short-term work disability benefits during 2008 to 2012, two study groups were identified as described below.

1) Mild PAD: This group has an ICD-9CM diagnostic code for PAD and PAD-related conditions occurring at any time between 2008 and 2012 as outlined in Figure 1 in the online appendix but no evidence of PAD-specific treatments.
2) Moderate/Severe PAD: This group has a PAD diagnosis as outlined above, but also has DRG, procedure or CPT-4 codes indicating treatment such as revascularization, amputation
or other procedures associated with moderate to severe PAD occurring at any time between 2008 and 2012 as outlined in Figure 1 in the online appendix.

Individuals with less than one year of medical history prior to the index event (a PAD diagnosis) were excluded from the study. Among 30,987 individuals identified with a PAD diagnosis between 2008 and 2012, 1,589 were categorized as moderate/severe and 29,398 as mild PAD cases.

## Measurement and Methods

THE PRIMARY OUTCOME OF INTEREST was short-term work disability (STD). Two sources of data are used to establish STD experience: 1) the benefits eligibility file establishes whether the individual was eligible to receive benefits in any given month between calendar years 2008 and 2012 and 2) the

STD claims file establishes whether a claim was filed (incidence established by date of claim) and the length of the claim in days (date claim closed). We tracked incidence of disability and duration for each disability episode for each of the years 2009-2012 subsequent to the index year 2008. STD incidence is
a 1/0 dichotomous variable where " 1 " indicates that an individual filed an STD for any cause during the referenced time frame and "O" indicates that an STD was not filed. STD duration represents the number of days that an individual is on short-term work disability in the referenced year.

Models of STD incidence rely on the full sample and utilize logistic regression modeling to predict the incidence of the dichotomous " $1 / 0$ " STD incidence variable. Models of STD duration rely on sub-samples of those individuals who have experienced an STD incident and utilize multivariate regression analysis to model the continuous STD duration variable measured in days. A final
set of analyses models the cumulative sum of STD days between the referenced data years.

The primary explanatory variable of interest is whether an individual has mild or moderate/severe PAD. Statistical control is used in multivariate regression models to account for the effects of age, sex and comorbidities on short-term work disability. Three age groups were constructed representing ages 18 to 34 , ages 35 to 49 and ages 50 and over. Comorbidity, ranging between 1 and 16, was measured as a count of major diagnostic categories associated with each individual's medical utilization over the study period.

## Descriptive Results

TABLE 1, ON THE FOLLOWING PAGE DISPLAYS OVERALL DESCRIPTIVE STATISTICS AND significant differences between the mild PAD group compared with the moderate/ severe PAD group.

[^0]Among the three age groups there were fewer individuals ages 18 to 34 , more males and a higher degree of comorbidity in the moderate/ severe PAD group compared with the mild PAD group. Across all STD incidence and duration measures there were significant differences between the mild PAD group compared with the moderate/severe

PAD group. Incidence of STD ranges between 12\% and 14\% year-by-year for the mild PAD group compared with $18 \%$ to $20 \%$ for the moderate/severe group. STD durations ranged between 7 and 9 days year-by-year for the mild PAD group compared with 12 to 14 days for the moderate/severe PAD group.

Table 2 displays overall descriptive statistics across the STD outcome by year.

Out of 30,987 individuals diagnosed with PAD during the study period, 3,921 experienced an STD incidence in 2009, 4,143 in 2010, 4,270 in 2011 and 4,423 in 2012. This represents $13 \%$ and $14 \%$ of individuals filing for an STD claim
between 2009 and 2012. Those STD episodes lasted between 57 and 64 days in any given year. On average, $16 \%$ of the sample were ages 18 to 34 years, 52\% ages 35 to 49 years and $31 \%$ age 50 and above. Males represent $57 \%$ of the sample.

The first set of four models exclude the comorbidity control, followed by a second set including the comorbidity control. In the first set of models the odds of filing a disability claim for the moderate/severe PAD group compared with the mild group ranges between 1.6 and 1.7
across the four years ( p <.0001). In the second set controlling for comorbidity the odds slightly diminish to between 1.3 and 1.4 greater odds for the moderate group filing a claim compared with the mild group with the odds remaining statistically significant ( $p<=.001$ ).

| age5Oplus | -0.573 | 3.167 | -0.180 | 0.856 |
| malerecode | 8.567 | 2.197 | 3.900 | $<.0001$ |
| maxMDC0812 | 4.815 | 0.458 | 10.520 | $<.0001$ |

For the models without comorbidity, individuals with moderate/severe PAD experience approximately 7.5 to 10 additional days of disability in any given year compared with those with mild PAD ( $p<=.03$ to marginal significance $p<=.07$ ). However, once comorbidity is added, the effect of
moderate/severe PAD diminishes and is no longer statistically significant. As comorbidity increases by 1 unit (i.e., each additional major diagnostic group represented by medical utilization) individuals experience 3 and 5 additional days of disability ( $p<.0001$ ).

## Cumulative Bias Tests

As a test of potential sample bias over time, three samples were tested representing cumulative disability days for four years (2009 to 2012), three years (2010 to 2012) and two years (2011 to 2012) as represented in Table 5.

## TABLE 5: MODELS OF CUMULATIVE SHORT-TERM DISABILITY DURATION FOUR YEARS (2009 TO 2012)

## TABLE 5: MODELS OF CUMULATIVE SHORT-TERM DISABILITY DURATION TWO YEARS (2011 TO 2012)

MODELS OF CUMULATIVE SHORT-TERM DISABILITY DURATION
DEPENDENT VARIABLE: DAYSABSSTD2012. ( $N=4,270$ )

|  | N | Mean | Std Dev | Minimum | Maximum |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Overall | 4270.000 | 90.187 | 108.154 | 1.000 | 1431.000 |
| Mild PAD | 3972.000 | 89.220 | 107.799 | 1.000 | 1431.000 |
| Moderate/severe <br> PAD | 298.000 | 103.077 | 112.180 | 1.000 | 552.000 |

| Parameter | Estimate | Standard Error | t Value | Pr $>[\mathrm{t}]$ |
| :--- | :--- | :--- | :--- | :--- |
| Intercept | 90.3370 | 4.0339 | 22.3900 | $<.0001$ |
| moderatePAD5yr | 12.9099 | 6.5030 | 1.9900 | 0.0472 |
| age35to49 | 0.1500 | 4.5244 | 0.0300 | 0.9736 |
| age50plus | -12.0144 | 4.9007 | -2.4500 | 0.0143 |
| malerecode | 5.7527 | 3.3530 | 1.7200 | 0.0863 |

WITH COMORBIDITY

| Parameter | Estimate | Standard Error | t Value | $\operatorname{Pr}>[\mathrm{t}]$ |
| :--- | :--- | :--- | :--- | :--- |
| Intercept | 15.9239 | 6.7467 | 2.3600 | 0.0183 |
| moderatePAD5yr | 5.3463 | 6.3913 | 0.8400 | 0.4029 |
| age35to49 | -4.8151 | 4.4448 | -1.0800 | 0.2787 |
| age50plus | -19.5125 | 4.8298 | -4.0400 | $<.0001$ |
| malerecode | 17.1893 | 3.3888 | 5.0700 | $<.0001$ |
| maxMDC0812 | 9.5055 | 0.6987 | 13.6000 | $<.0001$ |

The overall duration model findings hold with the moderate group having 13,20 and 23 more days of disability for each of the respective samples ( 2,3 and 4 years) compared with the mild PAD group ( $\mathrm{p}<=.05$ ). As with the year-by-year samples, once comorbidity is
controlled, the effect of the moderate/severe group is no longer significant. For each additional comorbidity, duration increases as follows: 9.5 days for the 2-year sample, 14 days for the 3 -year sample and 18 days for the 4-year sample (p<.0001).

## Limitations

STD INCIDENTS ARE FOR "ANY CAUSE", not restricted to PAD, although all individuals in this study have been diagnosed with PAD. Although we control for the count of
comorbidities we are not controlling for types of comorbidities which may be associated with the incidence and duration of STD.

## Discussion

EVEN ACCOUNTING FOR COMORBIDITY, HAVING MODERATE TO SEVERE PAD compared with mild PAD significantly affects the incidence of short-term work disability. If PAD cases can be managed in a way that prevents mild cases from becoming moderate/severe then employees and employers may benefit from less work disruption due to fewer cases of short-term work disability. Once an STD case begins, those with moderate to severe cases of PAD fare worse than mild cases in terms of duration in lost work days but once comorbidity is factored in the effect of the moderate/severe group disappears. Comorbidity is a critical factor to consider in both the incidence and duration of short-term work disability. ${ }^{21}$ Further research should investigate the relationship between comorbid condition type and work disability as well as the potential need to target specific age groups given the statistically different outcomes for the 35 to 49 age group in STD duration compared with the youngest group. Since the above age 50 group often
displayed no difference compared with the youngest group it suggests the middle group (aged 35 to 49) may need focused study and attention when it comes to medical treatment for PAD and potential economic effects beyond treatment costs. Other research has shown significant relationships between socioeconomic status and PAD. ${ }^{22}$ Guideline development efforts and related research have suggested that more attention should also be focused on preventive therapies and guideline adherence across populations. ${ }^{23,24,25,26,27}$ By adopting a patient-centered approach to prevention, treatment access and improved outcomes we should expect greater focus on functional and quality of life outcomes that matter to individuals. For those in the workforce, being able to attend work, perform well on the job and stay at work or return to work in a timely and healthy fashion should a period of work disability occur is critical for the continued physical and socioeconomic health of the individual. ${ }^{28}$
